

4 Path integral quantization of (non-abelian) gauge theories

4.1 General setting

- Recall first the basic structure introduced in Ch. 12 of QFT I:

- Let $\psi(x)$ be some field transforming in some repr. of some matrix group G (e.g. the fund. of $SU(N)$)

$$\psi(x) \rightarrow U(x)\psi(x).$$

- $D_\mu \psi \rightarrow U D_\mu \psi$ if $D_\mu = \partial_\mu + iA_\mu$

where $A_\mu \in \text{Lie}(G)$ and $iA_\mu \rightarrow U(\partial_\mu U^{-1}) + U iA_\mu U^{-1}$.

- We then introduced a field strength $F_{\mu\nu} \equiv \frac{1}{i} [D_\mu, D_\nu]$ transforming as $F_{\mu\nu} \rightarrow U F_{\mu\nu} U^{-1}$.

- The Lagrangian for A_μ is $\mathcal{L} = -\frac{1}{2g^2} \text{tr}(F_{\mu\nu} F^{\mu\nu})$

(coupled to fermions through $\mathcal{L}_f = \bar{\psi} (iD - m) \psi$.)

- In the non-abelian case, even the theory without ψ is non-trivial (in contrast to ED). To see this, write

$$A_\mu = A_\mu^a T^a ; \quad F_{\mu\nu} = F_{\mu\nu}^a T^a \quad \& \text{rescale } A_\mu \rightarrow g A_\mu.$$

- It follows that

$$\mathcal{L} = -\frac{1}{4} F_{\mu\nu}^a F^{\mu\nu a} ; \quad F_{\mu\nu}^a = \partial_\mu A_\nu^a - \partial_\nu A_\mu^a - f^{abc} A_\mu^b A_\nu^c$$

$$\mathcal{L} = \mathcal{L}_0 + \mathcal{L}_{\text{int.}}$$

where $\mathcal{L}_0 = -\frac{1}{4} [\partial_\mu A_\nu^a - \partial_\nu A_\mu^a] [\dots]$; $\mathcal{L}_{\text{int.}} > A^3 \& A^4$ terms.
 $\underbrace{\text{like ED}}$, but with $\dim(G)$ fields

- Thinking of A_μ^a as of a set of bosonic fields, we are tempted to appeal to our detailed discussion of the scalar field and to write

$$\langle T A_\mu(x_1) A_\nu(x_2) \dots \rangle = \frac{\int \mathcal{D}A A_\mu(x_1) A_\nu(x_2) \dots e^{iS}}{\int \mathcal{D}A e^{iS}}$$

$$(S = \int d^4x \mathcal{L}).$$

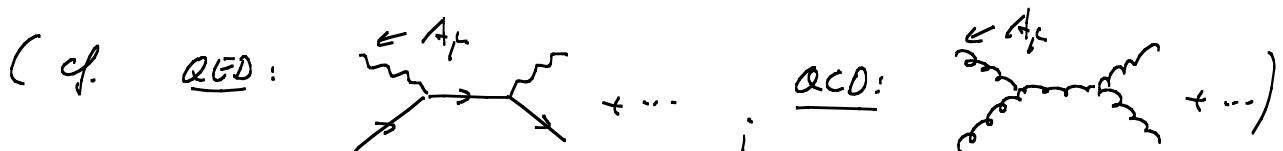

From this, we would like to derive scattering amplitudes of the non-abelian gauge bosons (e.g. gluons in the case $G = SU(3)$).

- An immediate problem that we are facing is gauge invariance: Phys. scatt. amplitudes are gauge-inv., while $T A_\mu(x_1) \dots$ isn't. In ED, we dealt with this by looking only at the scattering of phys. photons:

- Fourier-transforming w.r.t. x_i
- Setting the mom. introduced in this way "on shell" ($k^2 = 0$)
- contracting with a phys. polarization:

$$\tilde{A}_\mu(k) \rightarrow \epsilon^\mu(k) \tilde{A}_\mu(k).$$

- In QCD, this is also done, but it's not quite sufficient: It is necessary to set all other particles in a given amplitude on shell & to contract with phys. polarizations to ensure gauge-inv. w.r.t. a given ext. gluon.

This is a result of more complicated structure of diagrams (gluon-gluon-interactions).

- Even if this is done, gauge-inv. is only ensured "to leading order":

- Recall: $iA_\mu \rightarrow U(\partial_\mu U^{-1}) + U iA_\mu U^{-1}$

infinitesimally, with $U = e^{-iK} \approx 1 - iK$

$$\Downarrow$$

$$A_\mu \rightarrow A_\mu + \partial_\mu K - i[X, A_\mu]$$

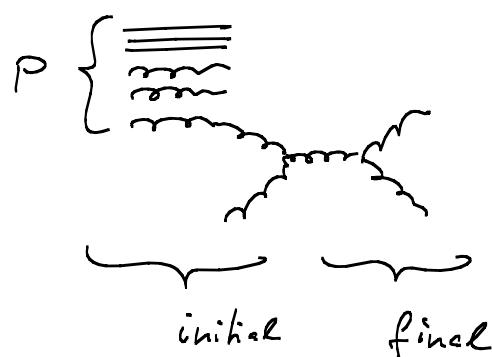

in pert theory, it is natural to rescale $A_\mu \rightarrow gA_\mu$ (and correspondingly $X \rightarrow gX$)

$$\Downarrow$$

$$A_\mu \rightarrow A_\mu + \partial_\mu K - ig[X, A_\mu]$$

This extra (w.r.t. QED), higher-order piece does not disappear by going on shell & using phys. polarizations.

- In fact, this gauge-inv problem of scattering amplitudes with gluons has a deeper phys. origin: gluons are not the right incoming/outgoing states; they are confined in color neutral states (nucleons, mesons, glueballs).
- Pragmatically speaking, the LHC (& other such machines) are nevertheless (to a very large extent) machines for scattering gluons. However, one needs to characterize the incoming photons as collections of very energetic gluons

& sum over all final states (in a certain well-defined way, e.g. defining jets).

- Quantitatively, this is encoded in the so-called "gluon distribution function" (e.g. of a proton), to be defined in more detail later. This quantity replaces the free incoming gluon and has to be defined (and, in principle, calculated) order by order in g . It is only in this procedure that gauge-invariance for incoming gluons is eventually fully recovered.
- Anticipating this procedure of
 - convoluting cross-sects. with $\underbrace{\text{quark/gluon distributions}}_{\text{parton}}$
 - & using jet definitions / fragmentation facts / complete final state sums for the outgoing partons,

we will now simply assume that it is sufficient for us to understand how to calculate

$$\langle 0 | T O[\hat{A}] | 0 \rangle = \frac{\int dA O[A] e^{is[A]}}{\int dA e^{is[A]}},$$

where O is a gauge-inv. expression (an observable) of our non-abelian gauge-th. [We will apply this to $T A_{\mu_1}(x_1) A_{\mu_2}(x_2) \dots$, which is justified with the caveats explained above.]

- A field-theoretically simpler and cleaner approach would be to directly consider the scattering of color neutral objects,

i.e. $T A_{\mu_1}(x_1) A_{\mu_2}(x_2) \dots \rightarrow T C(x_1) C(x_2) \dots$

\uparrow
some operator built from
 A 's which is gauge-inv ...

... and has non-vanishing overlap with a glueball:

$$\langle 0 | C(x) | \text{glueball} \rangle \neq 0.$$

- One can in principle properly normalize this operator (calculate the β -factor, as we did for the fundamental fields) and extract scat. amplitudes from green-fcts. for $C(x)$ à la LSZ. This might even be practically doable for certain heavy mesons ($b\bar{b}$ -Bound states). It is certainly not doable for glueballs, photons etc. since for such "light" objects pert. theory breaks down. Thus, even though

$$O[A] = T C(x_1) C(x_2) \dots$$

is a nice way to use our (to be described) procedure for calculating non-abelian functional integrals, it is not the most relevant one practically.

- Let us finally give an even simpler (and, with a few important exceptions, even more useful) gauge-inv. observable for testing non-abelian gauge theories:

- consider $L_{\text{gauge-th.}} + L_\varphi + \underbrace{L_{\text{int}}}_{\text{free real scalar}}$

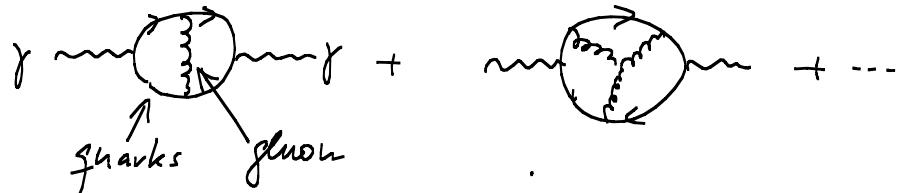

with, e.g., $L_{\text{int.}} = \lambda \varphi \text{tr } F^2 \Rightarrow \dots \text{---} + \text{other vertices}$

- There are now obviously gauge-inv. observables corresponding to φ - φ -scattering, induced by the coupling of φ to gluons:

$$\langle T \varphi_1 \varphi_2 \varphi_3 \varphi_4 \rangle \sim \text{---} \text{---} + \dots$$

$$\text{with } \langle T\varphi_1 \dots \varphi_4 \rangle \sim \int D\varphi D\bar{\varphi} \varphi_1 \dots \varphi_4 e^{iS} / \int D\varphi D\bar{\varphi} e^{iS}. \quad 42$$

- This very simple situation does in fact arise in practice since, e.g., QCD interactions correct the photon self-energy (and many processes involving photons):

In summary: It makes sense and has many phys. applications to calculate

$$\int DA \mathcal{O}(A) e^{iS[A]}$$

for gauge-inv. functionals \mathcal{O} of the gauge field $A_\mu(x)$.

4.2 Faddeev-Popov method

- We immediately anticipate a fundamental problem in the evaluation of funct. integrals of the type given above (i.e. $\int DA$ with gauge-inv. integrand):

- recall $iA_\mu \rightarrow iA_\mu^U = U(\partial_\mu U^{-1}) + iUA_\mu U^{-1}$
with $U = e^{-igX}$

- think of $\int DA$ as $\int_{\substack{\text{all } A \text{ not} \\ \text{related by a gauge trf.}}} D\lambda DX$.

- obviously, $\int DX$ will be divergent since the integrand does not depend on X .
- also obviously, this problem is an artifact of pert. theory, since really the gauge group is

compact ($U(1) \sim S^1$, $SU(2) \sim S^3$; etc.), i.e. for sufficiently large λ the gauge br. is trivial (just like $e^{2\pi i} = 1$). However, in pert. theory we only think in terms of Taylor expansions of all fields about the (trivial) vacuum ($A_\mu = 0$). Thus, we never see the compactness of the gauge group.

- Note: In a non-pert. definition, e.g. on the lattice, the problem is not present and $\int dA$ can be (numerically) evaluated without worrying about the gauge freedom.

- Note: Technically, we already encountered the problem in QED: If we write

$$iS[A] = - A_\mu (\mathcal{D}^{-1})^{\mu\nu} A_\nu ,$$

it turns out that $(\mathcal{D}^{-1})^{\mu\nu}$ has zero-eigenvals and is hence not invertible. We fixed this by choosing a gauge (and we will do so again, just in the path-int. approach).

- We will "fix the gauge" by demanding $G(A) = 0$ for some (non-gauge-inv.) fct. of A . A typical fct. is

$$G(A) = \partial^\mu A_\mu - w$$

\uparrow \uparrow
any Lie-alg.-valued fct.
This is Lie-alg. valued!

- Use $1 = \int dX \delta[G(A^\mu)] / \left| \det \left(\frac{\delta G(A^\mu)}{\delta X} \right) \right|$

in analogy to $1 = \int dx \delta(f(x))/f'(x)$.

(Note: By its definition via

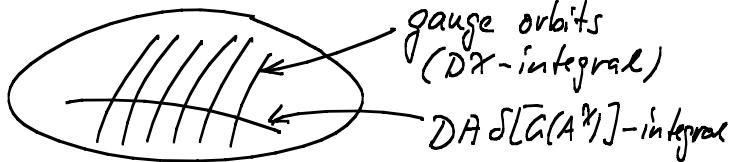

$$\delta G(A^X)(x) = \int d^4y \cdot \frac{\delta G(A^X)(x)}{\delta X(y)} \cdot \delta X(y) + \dots$$

$\frac{\delta G(A^X)}{\delta X}$ is an operator in the space of Lie-alg.-valued fcts. and its der. is well-defined (with appropriate UV/IR-regularization).)

• Hence:

$$\langle T O(A) \rangle = \frac{\int DX \int DA \delta[G(A^X)] / \det\left(\frac{\delta G(A^X)}{\delta X}\right) | O(A) e^{iS[A]}}{\int DX \int DA \delta[G(A^X)] / \det\left(\frac{\delta G(A^X)}{\delta X}\right) | e^{iS[A]}}$$

Intuitive: Space of all gaug-field config.s.:

- We now focus on the numerator (The denominator follows for $O(A) = 1$).

- Use $O(A) e^{iS[A]} = O(A^X) e^{iS[A^X]}$.

- Use $\int DA = \int DA^X / \det\left(\frac{\delta A^X}{\delta A}\right)^{-1} = \int DA^X$

at linear order in X , this has the form

$1 + M$, with M an antisymm. matrix. Thus, $\det(1 + M) = 1$ at lin. order in X . For finite gauge-hfs. which can be built by many infinitesimal gauge-hfs. (and we consider only those!) it then follows that

$$\det\left(\frac{\delta A^X}{\delta A}\right) = 1.$$

(Problem: Proof the above by calculating $\frac{\delta A^X}{\delta A}$ explicitly at lin. order in X .)

$$\Rightarrow \langle T O(A) \rangle = \frac{1}{Z[O]} \int D\chi \int D\chi' \delta[G(A^\chi)] \det \left(\frac{\delta G(A^\chi)}{\delta \chi} \right) |O(A^\chi) e^{iS[A^\chi]} \right|_{\chi'=0}$$

$$= \left| \det \left(\frac{\delta G(A^{\chi+\chi'})}{\delta \chi'} \right) \right|_{\chi'=0}$$

- rename $A^\chi \rightarrow A$

- drop $\int D\chi$ (just a divergent prefactor)

- rename $\chi' \rightarrow \chi$

$$\Rightarrow \langle T O(A) \rangle = \frac{1}{Z[O]} \int D\chi \delta[G(A)] \det \left(\frac{\delta G(A^\chi)}{\delta \chi} \right) |O(A) e^{iS[A]} \right|_{\chi=0}$$

- We are now, in principle, finished:

The gauge-freedom is fixed; Our path-int. is well-defined
(as far as gauge-freedom is concerned).

- At a technical level, two issues remain:

① Working with fields satisfying $\partial A = \omega$ is inconvenient.

② $\det(\delta G/\delta \chi)$ has to be calculated.

① Since nothing really depends on $G = \partial A - \omega$ (and hence on ω), we can multiply by $\int D\omega e^{-i\frac{A}{2}\omega^2}$.

$$\int D\omega e^{-i\frac{A}{2}\omega^2}$$

$$\int d^4x \omega(x)^2$$

The ω -integration can then be performed using $\delta[\partial A - \omega]$, giving

$$\langle T O(A) \rangle = \frac{1}{Z[O]} \int D\chi \det \left(\frac{\delta G(A^\chi)}{\delta \chi} \right) |O(A) e^{i(S[A] - \frac{A}{2}(\partial A)^2)} \right|_{\chi=0}$$

↑
"gauge-fixing term"

② To evaluate the "Faddeev-Popov-determinant" $\det(\frac{\delta G}{\delta \chi})$,

we use

$$\det M = \int D\bar{\theta} D\theta e^{-\bar{\theta} M \theta}.$$

46

- We have

$$(A_\mu^\alpha)^a = A_\mu^a + \partial_\mu X^a + gf^{abc} X^b A_\mu^c \quad (\text{check this!})$$

and hence

$$\frac{\delta G(A^\alpha)}{\delta x^d} = \frac{\delta}{\delta x^d} \left(\partial A^a + \partial^2 X^a + gf^{abc} \partial^b (X^b A_\mu^c) \right)$$

and

$$M(x,y)^{ad} = \delta^{ad} \partial^2 \delta^a(x-y) + gf^{adc} \partial_x^b (\delta^a(x-y) A_\mu^c(x)).$$

- Calling the (unphysical!) fermionic fields ("ghosts") introduced in this procedure c & \bar{c} , we have

$$\det \left(\frac{\delta G}{\delta x} \right) = \int D\bar{c} Dc \exp \left[-i \int d^4x d^4y \bar{c}^a(x) \left\{ \delta^{ad} \partial^2 \delta^a(x-y) + gf^{abc} \partial_x^b (\delta^a(x-y) A_\mu^c(x)) \right\} \cdot c^b(y) \right].$$

- Thus, we have found

$$\begin{aligned} L_{\text{ghost}} &= \bar{c}^a \left[-\delta^{ab} \partial^2 - gf^{abc} \partial^b A_\mu^c \right] c^b \\ &\quad \text{acting on both } A \text{ & } c. \\ &= -\bar{c} \underbrace{\partial^b D_\mu c}_\text{Here} \quad (\text{Here we abbreviate} \\ &\quad \bar{c}^a c^a \text{ by } \bar{c}c.) \\ &= \partial_\mu c + [A_\mu, c] \end{aligned}$$

[This is the proper covariant derivative for a "field in the adjoint repres.", like c . To see this, note that under gauge hfs. $c = c^a T^a \rightarrow e^{-igX} c e^{igX} = c - ig[X, c] + \dots$ The gauge hf. $A_\mu \rightarrow A_\mu + \partial_\mu X + \dots$ compensates the term arising from ∂_μ acting on the X of $[X, c]$. However, our ghost Lagrangian is still not gauge-inv. because of the extra ∂^b .] Note: Using this concept of the covariant derivative of an adjoint field, one also has $A_\mu^\alpha = A_\mu + D_\mu X$.

Problem: Show that the lagrangian $\mathcal{L} = -\frac{1}{2} \text{tr}(D_\mu \varphi D^\mu \varphi)$ of a physical (bosonic) adjoint scalar is gauge-invariant and work out the Feynman-rules (vertices) for its coupling to A_μ^a . 87

Finally:

$$\langle TO(A) \rangle = \frac{1}{Z[0]} \int DA D\bar{c} Dc O(A) e^{iS[A] + iS_{gf}[A] + iS_{gh}[\bar{c}, c, A]}$$

where $\mathcal{L}_{gf} = -\frac{\lambda}{2} (\partial A)^2$ (covariant gauges, parameterized by A)

$$\& \quad \mathcal{L}_{gh} = -\bar{c} \partial^\mu D_\mu c .$$

4.3 Feynman rules

- We now introduce sources $j^\mu{}^a, \bar{\gamma}^a, \gamma^a$ for $A_\mu{}^a, c^a, \bar{c}^a$:

$$S \rightarrow S + \int d^4x (A_\mu{}^a j^\mu{}^a + \bar{\gamma}^a c^a + \bar{c}^a \gamma^a),$$

define a generating functional $Z[j^\mu{}^a, \gamma^a, \bar{\gamma}^a]$

$$\text{as } Z = \int DA D\bar{c} Dc \exp i[S + A_j + \bar{\gamma} c + \bar{c} \gamma],$$

write $S = S_0 + S_{\text{int}}$
 \uparrow quadratic \uparrow rest
in A & \bar{c}, c ,

define Z_0 on the basis of S_0 ,

$$\text{evaluate } Z_0[j, \gamma, \bar{\gamma}] = Z_0[0] \exp \left[-\frac{1}{2} A D^{-1} A - \bar{c} D_g c \right],$$

and derive Feynman rules for the calculation of tree-level ftrs.
(note that we will never need external ghosts!) from

$$Z[j, \gamma, \bar{\gamma}] = \exp[iS_{\text{int.}}(\frac{\delta}{i\delta j}, -i\delta\gamma, i\delta\bar{\gamma})] Z_0[j, \gamma, \bar{\gamma}].$$

instead of A, \bar{c}, c

(Always remember that c, \bar{c} , and hence $\gamma, \bar{\gamma}$, are scalars & Grassmann variables ("fermions").

Note that this is not in contradiction with the Spin-statistic-theorem since the ghosts are not phys. particles: We will always set $\gamma, \bar{\gamma}$ to zero in Z , so that ghosts appear only in loops.)

The result (including also fermions in the fund. repres.), given directly in momentum space, reads: (for $SU(N)$)

- incoming fermion	\rightarrow	$u(p)_i$	← "color" index
outgoing " "	\rightarrow	$\bar{u}(p)_i$	
incoming anti-ferm.	\leftarrow	$\bar{v}(p)_i$	yet to be derived!
outgoing " "	\leftarrow	$v(p)_i$	
- inc./outg. gauge boson	$m_k / \delta m$	$E_{jk}(k)^a / \epsilon_j^{*\dagger}(k)^a$	
- fermion propagator	$\xrightarrow[p]{}$	$\frac{i\delta_{ij}}{p-m+i\varepsilon}$	
- gauge boson prop.	$\xrightarrow[p]{}$	$i\delta^{\mu\nu} - \frac{\gamma_{\mu\nu} + (1-\gamma)h^\mu h^\nu/h^2}{h^2 + i\varepsilon}$	

Note: $-\frac{1}{2} \text{tr } F^2 \rightarrow -\partial_\mu A_\nu \partial^\mu A^\nu + \partial_\mu A^\mu \partial_\nu A^\nu$

$$-\frac{\lambda}{2} (\partial A)^2 \rightarrow -\lambda \partial_\mu A^\mu \partial_\nu A^\nu,$$

which combines to an inverse prop. with the structure

$$h^2 \gamma_{\mu\nu} - k_\mu k_\nu (1-\lambda)$$

with inverse $A\gamma^{\mu\nu} + Bk^\mu k^\nu$,

$$\begin{aligned} & \left(Ak^2 \gamma_{\mu}^{\nu} + (k^2 B - A(1-\lambda) - k^2 B(1-\lambda)) k_\mu k^\nu \right) k_\nu = \gamma_{\mu}^{\nu} \\ & \Rightarrow Ak^2 = 1 ; \quad \lambda k^2 B - A(1-\lambda) = 0 \end{aligned}$$

i.e. $\frac{\gamma^{\mu\nu}}{k^2} + \left(\frac{1-\lambda}{\lambda}\right) \frac{k^\mu k^\nu}{(k^2)^2}$.

With $\xi = \frac{1}{\lambda}$ this is the desired result.

$(\xi = 1 - \text{Feynman gauge} ; \xi = 0 - \text{Landau gauge})$

Covariant or covariant gauges

Note: Recall that λ emerged from

$$\int D\omega e^{-i\frac{\lambda}{2}\omega^2},$$

where $\omega = \partial_\mu A^\mu$ was the gauge fixing condition.

Hence $\lambda \rightarrow \infty$ (or $\xi \rightarrow 0$) corresponds to

$\partial_\mu A^\mu = 0$. Thus, the Landau gauge is the only "truly gauge-fixed gauge" among the cov. gauges. The others are in some sense "averaged", because of the non-trivial averaging over ω .

This special role manifests itself in the fact that the Landau-gauge propagator is transverse:

$$(\gamma^{\mu\nu} - k^\mu k^\nu/k^2) k_\nu = 0,$$

i.e. longit. gauge bosons don't propagate.

- ghost prop.

\rightarrow

$$\frac{i\delta^{ab}}{p^2 + i\varepsilon}$$

(remember the minus-sign for each fermion loop; derive this minus-sign in the path-int. approach!)

- fermion-gluon vertex

$$-ig \gamma_\mu T_{ij}^a$$

- 3-gluon-vertex

$$-gf^{a_1 a_2 a_3} \left\{ (k_1 - k_2)_{\mu_3} \gamma_{\mu_1 \mu_2} + \text{cyclic.} \right\}$$

- 4-gluon-vertex

$$\left[ig^2 f^{a_1 a_2 b} f^{a_3 a_4 b} \left\{ \gamma_{\mu_1 \mu_4} \gamma_{\mu_2 \mu_3} - \gamma_{\mu_1 \mu_3} \gamma_{\mu_2 \mu_4} \right\} + \text{cyclic permutations} \right]_{i=1,2,3}$$

- ghost-gluon-vertex

$$gf^{abc} p'_\mu$$

Problem: Derive them, especially the 3- & 4-gluon vertices!

Note: All of this, including the ghosts, applies trivially to the abelian case. However, the ghosts don't interact (no f^{abc} 's!).
