## Quantum Field Theory 1 – Problem set 13

Lectures: Jan Pawlowski J.Pawlowski@thphys.uni-heidelberg.de Tutorials: Felipe Attanasio F.Attanasio@thphys.uni-heidelberg.de Institut für Theoretische Physik, Uni Heidelberg tutorial date: week of 30.01.2023

Suggested reading before solving these problems: Chapter 7.1 in the script.

## Problem 1: Ultraviolet Landau pole in four-dimensional $\phi^4$ theory

In the lecture, you have calculated the  $\beta$  function (Gell-Mann & Low, 1954) for the coupling in  $\phi^4$  theory in four spacetime dimensions to be

$$\beta(\mu) = \mu \frac{d}{d\mu} \lambda = \frac{3}{16\pi^2} \lambda^2 \,. \tag{1}$$

where the renormalization condition fixes  $\lambda = \lambda_{\text{phys}}$  at the momentum scale  $\mu$ .

- a) Solve the differential equation (1) and explicitly give the coupling function  $\lambda(\mu)$  as a function of the momentum scale  $\mu$ .
- b) Suppose the value of the coupling  $\lambda$  is known at an infrared momentum scale  $\mu_{\rm IR}$  to be  $\lambda(\mu_{\rm IR}) = \lambda_{\rm IR} > 0$ . Show that for large  $\mu$  the coupling exhibits a singularity at a finite  $\mu_{\rm L}$ . Calculate  $\mu_{\rm L}$ .
- c) What is the value of the coupling if we demand  $\lambda < \infty \ \forall \mu$ ?

This is the Landau pole or triviality problem and it indicates that the theory becomes strongly coupled, i.e. perturbation theory predicts its own failure. A similar behavior is observed in QED, where  $\beta = e^3/(12\pi^2) + \dots$  Here, the Landau-pole is predicted to appear on energy scales much larger than the Planck scale,  $m_{\rm P} \sim 10^{19} \text{GeV}$ . The LHC operates at energies of the order of  $\sim 10^4 \text{GeV}$ .

## Problem 2: Infrared Landau pole in six-dimensional $\phi^3$ theory

Another perturbatively renormalizable theory is given by a scalar field with a cubic interaction term  $g\phi^3$  in six-dimensional spacetime. This should rather be considered as a toy model, however, it turns out that it shares a fundamental similarity with the theory of the strong interaction, i.e. Quantum Chromodynamics (QCD): it has a negative sign in the  $\beta$  function. Here, we will explore the consequences:

The  $\beta$  function for the coupling g in  $\phi^3$  theory in six spacetime dimensions is

$$\beta(\mu) = \mu \frac{d}{d\mu}g = -\frac{3}{256\pi^3}g^3.$$
 (2)

- a) Solve the differential equation (2) and explicitly give the coupling function  $g(\mu)$  as a function of the momentum scale  $\mu$ .
- b) Suppose the value of the coupling g is known at an infrared momentum scale  $\mu_{\text{IR}}$  to be  $g(\mu_{\text{IR}}) = g_{\text{IR}} > 0$ . Show that for large  $\mu$  the theory becomes weakly coupled.
- c) What happens at small momentum scales  $\mu < \mu_{IR}$ ?

This behaviour is called *asymptotic freedom*. In QCD, we have  $\beta = -\frac{g^3}{16\pi^2} \left(\frac{11}{3}N_c - \frac{2}{3}N_f\right)$  on one-loop level, where the number of colors is  $N_c = 3$  and asymptotic freedom can accordingly be observed for a number of fermion flavors  $N_f < 33/2$ .
