# Motivation : Divergence of perturbative expansions

Perturbative expansion in QFT over Feynman graphs

$$\log Z = \log \int [\mathcal{D}\phi] \exp - \int \left\{ \frac{1}{2} (\partial\phi)^2 + \frac{m^2}{2} \phi^2 + \frac{g}{4!} \phi^4 \right\}$$
  
" = " 
$$\sum_{G \text{ Feynman graph}} \mathcal{A}(G) g^{\text{#vertices}}$$

The perturbative expansion is a **divergent** power series (otherwise Z defined for Re(g) < 0, g = 0 boundary of analyticity domain).

Perturbative expansion only valid as an **asymptotic series** for  $g \rightarrow 0$  but does not allow for a definition of a QFT.

Origins of the divergence :  $\sum_{G \text{ order } n} \mathcal{A}(G) \sim n!$ 

• too many graphs of given order (instantons)

• too large graph amplitudes at given order (renormalons) Construction of QFT from its perturbative expansion usually addressed using Borel summation.

### Factorial growth of the number of Feynman graphs

Consider a simple integral analogue to the functional integral in quantum field theory ( $\text{Re}(g) \ge 0$ ) with asymptotic expansion

$$Z + \int_{\mathbb{R}} \frac{d\phi}{\sqrt{2\pi}} \exp \left\{ -\left\{ \frac{\phi^2}{2} + \frac{g\phi^4}{4!} \right\} \quad " = " \sum_{n=0}^{+\infty} (-1)^n a_n g^n \quad (1)$$

This integral counts **Feynman graphs** with **factorial growth**, thus impeding the convergence of the series (two many graphs)

$$a_n = \sum_{\substack{G \text{ graph}\\\text{with } n \text{ vertices}}} \frac{1}{\#\operatorname{aut}(G)} = \int_{\mathbb{R}} \frac{d\phi}{\sqrt{2\pi}} \exp\left\{-\left\{\frac{\phi^2}{2}\right\} \frac{\phi^{4n}}{(4!)^n n!}\right\}$$
(2)  
$$\sum_{\substack{n \to +\infty}} C(2/3)^n n!$$
(3)

From a physical viewpoint, the integral defines an analytic function for  $\operatorname{Re}(g) > 0$  such that the origin lies on the boundary of analyticity domain. If the series was convergent, it would make sense for  $\operatorname{Re}(g) < 0$  leading to an **unstable model**. Alternatively,  $g\phi^4$  cannot be treated as small for large field  $\phi_{2,2} = 0$ 

### Borel summability and instanton singularity

Starting with a possibly divergent series  $\sum (-1)^n a_n g^n$  asymptotic to a function F(g), we can attempt at recovering F using

$$F(g) = \frac{1}{g} \int_0^{+\infty} ds B(s) \exp(-s/g)$$
(4)

with 
$$B(s) = \sum_{n=0}^{+\infty} \frac{(-1)^n a_n}{n!} s^n$$
 the Borel transform.

This requires B(s) to be free of singularities on the positive real axis. After rescaling the field  $\phi \to \phi/\sqrt{g}$ 

$$Z = \frac{1}{\sqrt{g}} \int_{\mathbb{R}} \frac{d\phi}{\sqrt{2\pi}} \exp\left\{\frac{1}{g}\left(\frac{\phi^2}{2} + \frac{\phi^4}{4!}\right)\right\}$$
(5)  
$$= \frac{1}{\sqrt{g}} \int_0^{+\infty} \exp(-s/g) \int_{\mathbb{R}} \frac{d\phi}{\sqrt{2\pi}} \delta\left\{\frac{\phi^2}{2} + \frac{\phi^4}{4!} - s\right\}$$
(6)

The Dirac distribution leads to **instanton singularities** for classical solutions of the equations of motion with real and positive action.

#### The Nevanlinna-Sokal theorem on Borel resummation

Recall the Nevanlinna-Sokal theorem : If F is a analytic function in the disk  $\operatorname{Re}(1/g) > R^{-1}$  and  $\sum_n a_n g^n$  a formal power series such that

$$\left|F(g) - \sum_{k=1}^{n} a_k g^k\right| \le C\sigma^{-(n+1)} |g|^{n+1} (n+1)!$$
(7)

then F can be reconstructed from  $B(s) = \sum_{n} \frac{a_n}{n!} s^n$ 

$$F(g) = \frac{1}{g} \int_{0}^{+\infty} \exp(-s/g) B(s)$$
 (8)

### Combinatorial approach : Loop Vertex Representation

Basic idea (V. Rivasseau, arxiv 0706.1224) : expand the partition function over forests (= not necessarily connected graphs without loops) over instead of graphs and logarithm expanded over trees (connected components)

$$Z = \sum_{F ext{ forest}} \mathcal{A}_F(g) \qquad \Leftrightarrow \qquad \log Z = \sum_{T ext{ tree}} \mathcal{A}_T(g)$$

**Convergence of the expansion** possible because of power law growth (solving the "too many graphs" issue)

$$\# \begin{pmatrix} \text{trees of} \\ \text{order } n \end{pmatrix} \underset{n \to +\infty}{\sim} \kappa^n \quad \text{vs} \quad \# \begin{pmatrix} \text{graphs of} \\ \text{order } n \end{pmatrix} \underset{n \to +\infty}{\sim} n!$$

and power law bounds on tree amplitudes  $|\mathcal{A}_\mathcal{T}(g)| \leq C^n |g|^n$ 

Usual perturbative expansion recovered by further expanding  $A_T(g)$  in powers of g (addition of loops to T)

Open question in QFT but interesting results for random matrices.

## Random Matrices

Topological ribbon graph expansion of matrix integral

$$\frac{1}{N^2} \log \int DM \exp -N \left\{ \operatorname{Tr} M^2 + g \operatorname{Tr} M^{2p} \right\} = \sum_{\substack{G \text{ ribbon graph}}} \mathcal{A}_G g^{\#(\operatorname{vertices})} N^{\chi(G)}$$

with 
$$\chi = 2 - \text{genus} = \#(\text{vertices}) - \#(\text{edges}) + \#(\text{faces})$$

Ribbon Feynman graph (double line) dual to trianagulations

$$\operatorname{Tr} M^{3} = \sum_{i,j,k} M_{ij} M_{jk} M_{ki} \to \bigcup_{j_{k} \atop k} M_{ki}$$

Multiple occurence in physics as random Hamiltonians (spectra of heavy nuclei, JT gravity in the Schwarzian limit, ..) or topological expansion (large N QCD, 2d gravity, ...).

Main result : Uniform analyticity in a "Pac-Man" domain

For any  $\epsilon > 0$  there exists  $\eta > 0$  such that the LVE expansion

$$\frac{1}{N^2}\log\int DM\exp{-N\left\{\operatorname{Tr} M^2 + g^{p-1}\operatorname{Tr} M^{2p}\right\}} = \sum_{T\,\mathrm{tree}}\mathcal{A}_T(g,N) \quad (9)$$

is convergent and defines an analytic function for

$$g \in \left\{ 0 < |g| < \eta, |\arg g| < rac{\pi}{2} + rac{\pi}{p-1} - \epsilon 
ight\}$$
 (10)

It is bounded by a constant independent of N and Borel summable in g, uniformly in N (with a cut for p = 2).

Forest Formula (Abdesselam, Brydges, Kennedy, Rivasseau)  $\phi$  function of  $\frac{n(n-1)}{2}$  variables  $x_{ij} \in [0, 1]$  (edges between *n* vertices)

$$\phi(1,\ldots,1) = \sum_{\substack{F \text{ forest} \\ \text{on } n \text{ vertices}}} \int_0^1 \prod_{(i,j)\in F} du_{ij} \ \left(\frac{\partial^{\#(\text{edges in } F)}\phi}{\prod_{(i,j)\in F}\partial x_{ij}}\right) (v_{ij}) \ ,$$

where  $v_{ij}$  is the infimum of  $u_{kl}$  along the unique path from from *i* to *j* in *F* if it exists and 0 otherwise

• n = 2:2 forests (1) (2), (1)-(2),

$$\phi(1) = \phi(0) + \int_{0}^{1} du_{12} \left(\frac{\partial \phi}{\partial x_{12}}\right) (u_{12})$$
•  $n = 3$ :   
 $(3)^{\circ}, (3)^{\circ}, (3)^{\circ}, (4)^{\circ}, (5)^{\circ}, (5)^{$ 

# Tree expansion of the partition function

Then, one can rewrite the integral of the exponential over a variable  $\phi$  as a sum of multiple integrals over multiple variable  $\phi_1, \ldots, \phi_n$ 

$$Z = \int d\mu_{\mathcal{C}}(\phi) \exp\left\{-V(\phi)\right\} = \sum_{n=0}^{+\infty} \frac{(-1)^n}{n!} \int d\mu_{C_{ij}=1}(\phi_1, \dots, \phi_n) V(\phi_1) \cdots V(\phi_n) \quad (11)$$

In this formula,  $d\mu_{C_{ij}=1}(\phi)$  is a Gaussian measure with a covariance matrix whose entries are all equal to  $1 \Leftrightarrow \text{sets } \phi_1 = \cdots = \phi_n$ 

Replacing  $C_{ij} = u_{ij}$  for  $i \neq j$ , we can apply the forest formula

$$Z = \int d\mu_{C(u)}(\phi) \exp\left\{-V(\phi)\right\}\Big|_{u_{ij}=1} = \sum_{\text{forests } \mathcal{F}} \mathcal{A}_{\mathcal{F}}$$
(12)

Since  $\mathcal{A}_{\mathcal{F}} = \mathcal{A}_{\mathcal{T}_1} \cdots \mathcal{A}_{\mathcal{T}_c}$ , the logarithm reduces to a sum over trees

$$\log Z = \sum_{\text{trees } \mathcal{T}} \mathcal{A}_{\mathcal{F}}$$
(13)

### Tree expansion of the matrix integral

Let us apply the forest formula after rescaling the matrix as  $M \to M/g$ 

$$Z = \int dM \exp{-\frac{N}{g}} \left\{ \operatorname{Tr} M^{2} + V(M) \right\}$$
(14)  
$$= \sum_{n} \frac{(-1)^{n}}{n!} \int dM_{1} \cdots dM_{n} \exp{-\frac{N}{g}} \left\{ \sum_{1 \le i,j \le n} C_{ij}^{-1} \operatorname{Tr}(M_{i}M_{j}) \right\}$$
$$V(M_{1}) \cdots V(M_{1}) \bigcup_{\substack{C_{ij}=1\\ \text{sets } A_{i} = A_{j}}}$$
(15)  
$$= \sum_{F \text{ embedded forest}} \mathcal{A}_{F}$$
(16)

Then the free energy  $\log Z$  is a sum over **embedded** trees. It remains to bound the amplitudes and the number of trees.

# Morse-Palais change of variables

The Morse-Palais lemma states that any functional can be reduced to a quadratic one in the vicinity of its extrema. For the matrix integral, we set

$$K = M\sqrt{1 + M^{2p-2}} \qquad \Leftrightarrow \qquad M = K\sqrt{T(-K^{2p-2})}$$
(17)

with T the Fuß-Catalan function such that  $T(z) = 1 + zT^{p}(z)$ . For the matrix integral, it leads to

$$\int dM \exp{-\frac{N}{g}} \left\{ \operatorname{Tr} M^2 + \operatorname{Tr} M^{2p} \right\} =$$
(18)

$$\int dK \exp -\left\{ N \operatorname{Tr} K^2 + V_{eff}(K) \right\}$$
(19)

with an effective potential computed from the Jacobian

$$V_{eff}(K) = -\log \det \frac{\delta M}{\delta K} = -\operatorname{Tr}_{\otimes} \log \frac{\delta M}{\delta K}$$
 (20)

The derivative of the logarithm is a resolvent and analytic properties of T(z) lead to useful bounds on tree amplitudes

#### Effective potential and matrix derivative

For any single matrix function  $M = \sum_{n} a_{K}^{n}$ , the **matrix derivative** acting on matrices  $M_{N}(\mathbb{C}) \sim \mathbb{C}^{N} \otimes \mathbb{C}^{N}$  by left and right multiplication is defined as

$$\delta M = \sum_{n} \sum_{k=0}^{n-1} a_n K^k \, \delta K \, K^{n-1-k} \Leftrightarrow \frac{\delta M}{\delta K} = \sum_{n} \sum_{k=0}^{n-1} a_n K^k \otimes K^{n-1-k}$$
(21)

In our case with Fuß-Catalan function T

$$\frac{\delta M}{\delta K} = \frac{K\sqrt{T(-K^{2p-2})} \otimes 1 - 1 \otimes K\sqrt{T(-K^{2p-2})}}{K \otimes 1 - 1 \otimes K}$$
(22)

if  $e_i$  diagonalises K,  $Ke_i = \nu_i e_i$ , then  $e_i^{\dagger} e_j^{\dagger}$  diagonalises  $\frac{\delta M}{\delta K}$  and

$$V_{\rm eff}(K) = \sum_{i,j} \log \left| \frac{\nu_i \sqrt{T(-\nu_i^{2p-2})} - \nu_j \sqrt{T(-\nu_j^{2p-2})}}{\nu_i - \nu_j} \right|$$
(23)

# Fuß-Catalan generating function

Lagrange inversion formula leads to Fuß-Catalan numbers

$$T(z) = 1 + zT^{p}(z) \quad \Rightarrow \quad T(z) = \sum_{n} \frac{(np)!}{n!(np-n+1)!} z^{n} \quad (24)$$

ordinary Catalan numbers for p = 2 (counting *p*-ary trees) Some useful properties :

- T(z) analytic on the cut plane  $\mathbb{C} \left[\frac{(p-1)^{p-1}}{p^p}, +\infty\right]$
- behavior at infinity  $T(z) \sim -\left(\frac{1}{z}\right)^{1/p}$  '
- $T(z) \neq 0$  for finite z

On any domain  $\boldsymbol{\Omega}$  staying at a finite distance from the cut

$$|T(z)| \leq \frac{C_{\Omega}}{(1+|z|)^{1/p}}, \quad |T'(z)| \leq \frac{C'_{\Omega}}{(1+|z|)^{1/p+1}}, \dots$$
 (25)

(日)(1)<p

## Analyticity from counting trees

The number of labelled and embedded trees on n vertices is

$$\sum_{\substack{r_1-1+\dots+r_n-1\\=n-2}} \underbrace{(n-2)!}_{(r_1-1)!\cdots(r_n-1)!} \times \underbrace{(r_1-1)!\cdots(r_n-1)!}_{(r_1-1)!\cdots(r_n-1)!} \times \underbrace{(r_1-1)!\cdots(r_n-1)!}_{(r_1-1)!\cdots(r_n-1)!} = \frac{(2n-3)!}{(n-1)!}$$
(26)

Bounding each tree amplitude leads to a convergent series

$$|F| \leq \sum_{T} |\mathcal{A}_{T}| \leq \frac{(2n-3)!}{(n-1)!} \times \frac{|\lambda|^{n} [\kappa(\arg \lambda)]^{n}}{n!}$$
(27)

The factorial growth cancel so that the series has a finite radius of convergence, with  $\kappa(\arg \lambda) \propto \frac{1}{|\cos(\arg \lambda)|}$  for  $|\arg \lambda| < \pi/2$  (positivity of Gaußian measure)  $\Rightarrow$  not enough for Borel summation.

#### Analytic continuation from contour rotation

To accommodate a large range for arg  $\lambda$  let us rotate the matrix integral by and angle  $\alpha M \rightarrow \exp(i\alpha)M$  as well as all Cauchy contours with two constraints :

• positivity of the Gaußian measure  $\exp -\frac{\operatorname{tr} K^2}{g}$ 

$$-\pi/2 < \arg \lambda - 2\alpha < \pi/2 \tag{28}$$

- singularity of the Fuß-Catalan function  $Tig(-\kappa^{2p-2}ig)$ 

$$-\pi < (2p-2)\alpha < \pi \tag{29}$$

The maximal opening of the domain of analyticity is therefore

$$-\frac{\pi}{2} - \frac{\pi}{p-1} + \epsilon \le \arg \lambda \le \frac{\pi}{2} + \frac{\pi}{p-1} - \epsilon$$
(30)

・ロト・西ト・モン・モー シック

#### Bounds on the tree amplitude

Writing the effective potential as  $V_{\text{eff}}(K) = \text{Tr}_{\otimes} \log(1 - \Sigma)$  (acting in  $\mathbb{C}^N \otimes \mathbb{C}^N$ ), every vertex is represented as a double line graph with insertions of  $(1 - \Sigma)^{-1}$  or  $\frac{\partial \Sigma}{\partial K}$ , written as a contour integral. The tree amplitude  $\mathcal{A}_T$  involves E(T) + 2 faces and is a trace in  $\mathbb{C}^{\otimes (E(T)+2)}$ . Using  $|\text{Tr}(A)| \leq N^{\otimes (E(T)+2)} ||A||$ , it can be bounded as

$$\left|\mathcal{A}_{\mathcal{T}}\right| \leq N^{2} \prod_{i} \oint_{\Gamma_{i}} \left|du_{i}\right| \prod_{j} \left\|\mathcal{O}_{j}\right\|$$
(31)

where  $\mathcal{O}_j$  are the operators encountered around the vertices and contracted along the edges.

# Borel summability of the matrix model partition function

Borel summability follows from the **Nevanlinna-Sokal** theorem checking the two hypothesis :

- Analyticity on the circle tangent to the positive axis follows from the analyticity in the Pac-Man domain.
- The bound on the remainder can be obtained by recursively adding edges to the trees

$$\log Z = \sum_{k=0}^{n} (-1)^{n} a_{n} g^{n} + R_{n+1}(g, N)$$
(32)

The remainder is a over trees with at least n + 1 - k edges on which k edges have been added using the representation

$$\int d\mu_{C}(K) f(K) = \exp\left(\frac{1}{2} \sum_{ij} C_{ij} \frac{\partial^{2}}{\partial K_{i} \partial K_{j}}\right) f(K) \Big|_{K=0} \quad (33)$$

## Towards a similar approach in Quantum Field Theory

Change of variables from Morse-Palais lemma : reduction of a functional around a critical point in Hilbert space to a quadratic form  $S[\phi] = \langle \chi(\phi), \chi(\phi) \rangle$ 

$$\int \left\{ \frac{1}{2} (\partial \phi)^2 + \frac{m^2}{2} \phi^2 + \frac{g}{4!} \phi^4 \right\} = \int \left\{ \frac{1}{2} (\partial \chi)^2 + \frac{m^2}{2} \chi^2 \right\}$$

leading to the non local effective potential (Jacobian)

$$V_{ ext{eff}}[\chi] = \log \det rac{\delta \phi}{\delta \chi} = ext{Tr} \, \log rac{\delta \phi}{\delta \chi}$$

Difficulty : find suitable **cut-off independent bounds**. Matrix model with kinetic term (Grosse-Wulkenhaar model)

$$\int DM \exp - \left\{ \operatorname{Tr} AM^2 + g \operatorname{Tr} M^4 \right\}$$

2d case by V. Rivasseau and Z.T. Wang arxiv1805.06365.
